FG SDC = SNOOP = frame snoop (English) = snoop (in SR context) 11:48
A bit more precisely:

$\boxed{\text{FG SDC} \equiv \text{SNOOP} \equiv \text{frame snoop (English)}} \equiv \text{snoop (in SR context)}$ 11:48
since "frame" as an adjective modifies the English dictionary definition of the noun "snoop" to give it a precise definition within SR, that being an FG SDC. The word "snoop" by itself then becomes a contextual abbreviation for "frame snoop." 11:48

I'm no longer so sure Doppler by itself fixes frame cell ratios, if nothing else because one ~~can~~ ^{must} 11:48 draw in ^{the} ~~the~~ Doppler size with the rectangular cell, as the tic marks on the cell sides.

(I think I've defaulted to four sections — three tic marks — per cell side simply because it provides a clear visual feel for the Doppler issue.). Experimental observations of Doppler emissions should of course resolve this issue unambiguously; it's just that rectangle normalization as an abstract problem does not seem to provide any unambiguous scale info, whether it is done with or without Doppler.

Assuming μ conservation, $M^2 = m^2 + p^2$ (or in the more traditional form, $E^2 = m^2 c^4 + p^2 c^2$) will of course (?) force scaling, but that ~~sort of~~ 11:48 defeats the whole purpose of the derivation, since Einstein derived that after (in his next paper) he had worked out the SR transformation based solely on frame equivalence and the constant speed of light. (Maybe energy conservation should be brought in? 11:48)

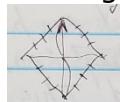

[2011-07-30.11:17 Sat] [11:48]
[FG SDC = SNOOP = frame snoop (English) = snoop (in SR context) / Doppler alone is insufficient]

A bit more precisely:

FG SDC \equiv SNOOP \equiv frame snoop (English) \equiv snoop (in SR context)
since "frame" as an adjective modifies the English
dictionary definition of the noun "snoop" to give
it a precise definition within SR, that being an FG SDC.
The word "snoop by itself then becomes a
contextual abbreviation for "frame snoop."

I'm no longer so sure Doppler by itself fixes
frame cell ratios, if nothing else because one
must draw in the Doppler size with the
rectangular cell, as the tic marks on the cell sides.

(I think I've defaulted to the four sections —
three tick marks — per cell side simply
because it provides a clear visual feel
for the Doppler issue.). Experimental observations
of Doppler emissions should of course resolve this
issue unambiguously; it's just that rectangle
normalization as an abstract problem does not
seem to provide any unambiguous scale info,
whether it is done with or without Doppler.

Assuming μ conservation, $\mu^2 = m^2 + p^2$ (or in
the more traditional form, $E^2 = m_0^2 c^4 + p^2 c^2$) will
of course (?) force scaling, but that sort of
defeats the whole purpose of the derivation,
since Einstein derived that after (in his next
paper) he had worked out the SR transformation
based solely on frame equivalency and the constant
speed of light. (Maybe energy conservation should be brought in?)
